Difference Between ORDER BY and GROUP BY.

ORDER BY

- 1.) Used to display information either in ascending or descending order.
- 2.) Used for sorting data in the table.
- 3.) Not mandatory to use aggregate functions with order by.
- 4.) Eg. → select * from student ORDER BY marks;

GROUP BY

- 1.) Used to group data on the basis of particular column.
- 2.) Used for grouping of data.
- 3.) Mandatory to use aggregate functions in order to use GROUP BY command.
- 4.) Eg. → select name, sum(marks) from student GROUP BY name;

Difference between WHERE and HAVING

WHERE

- 1.) Used for selecting specific row/rows based on the condition.
- 2.) It can be used without GROUP BY.
- 3.) WHERE clause can't contain aggregate functions.
- 4.) Select * from student WHERE marks > 80;

HAVING

- 1.) HAVING clause can't be used without GROUP BY command.
- 2.) HAVING clause selects rows after grouping.
- 3.) Contains aggregate functions.
- 4.) eg. → select name, max(marks) from student GROUP BY name having max(marks) > 70;

(3)

GROUP BY

Syntax:-
Select (column name), aggregate func.
from (tablename) GROUP BY (column name);

- Example:-
- 1.) Select name, marks from student GROUP BY name;
 - 2.) Select name, marks from student where marks ≥ 70
GROUP BY name;
 - 3.) Select name, sum(marks) from student GROUP BY name;
 - 4.) " " " " " " " " " " having sum(marks) > 75 ;
 - 5.) Select name, count(city) from student group by name;
 - 6.) " " " " " " " " " " having count(city) > 1 ;

(4)

SQL Joins.

⇒ These ~~sql~~ SQL joins are used to join rows from two or more tables.

1.) Cartesian Product. → used to join rows from one table to another.

⇒ Also called cross-join or cross-product.

⇒ It's a binary operation and represented as $\boxed{\times}$.

eg. $A = \{1, 2, 3\}$

$B = \{a, b, c\}$

$C = A \times B$

↳ Cartesian product.

| A | B | = C = A × B |
|---|---|-------------|
| 1 | a | (1, a) |
| 2 | b | (1, b) |
| 3 | c | (1, c) |
| | | (2, a) |
| | | (2, b) |
| | | (2, c) |
| | | (3, a) |
| | | (3, b) |
| | | (3, c) |

Eg. → We have 2 tables named stud and games.

stud.

| Rollno. | name. |
|---------|-------|
| 1 | A |
| 2 | B |
| 3 | C |

games.

| gno | game |
|-----|--------|
| 11 | Tennis |
| 12 | Hockey |

Syntax:- select * from table1, table2;

eg. → select * from stud, games;

② Equi-Join:- It uses [=] operator and used to establish the relationship between two tables on the basis of primary key and foreign key concept.

Syntax: Select * from table1, table2 where
table1.primary key = table2.foreign key;
or table1.columnname = table2.columnname;

(6)

DELTA Pg No.

Foreign Key

Example.

Primary Key.

↓ Student

| RollNo. | Name | City | Marks |
|---------|------|-------|-------|
| 1 | A | Delhi | 70 |
| 2 | B | Goa | 20 |
| 3 | C | Vizag | 30 |
| 4 | D | Mum | 50 |

Primary Key

Books

↓ Books

| BookID | RollNo. | BookName |
|--------|---------|----------|
| 10 | 1 | C5 |
| 20 | 2 | Chem. |
| 30 | 4 | PHY. |

Select * from student, books where
student.rollno = books.rollno ;

We can use alias name as well, ~~at~~ let's say
s for student table and b for books table.
So, the same query can be written as.

⇓

Select * from student s, books b where
s.rollno = b.rollno ;

(7)

Natural JOIN!—

It is equivalent to Equi-Join
only difference it eliminates the
duplication of the same column name
used for primary and foreign key.

Syntax!—

select * from table1 NATURAL JOIN table2;

eg. → select * from student NATURAL JOIN Books;
